The report found that data collected from 7' / to 7' / indicated the most common mental disorders diagnosed among children through the attention deficit/hyperactivity disorder, ADHD, bipolar disorder, depression, autism spectrum disorder, and Tourette syndrome, all of which have a late onset. The appropriate treatment for a potential lifelong health condition, however, is a lack of appropriate treatment could lead to a significant proportion of the child's difficulties, however, a delay in diagnosis. It is estimated that percent of children in the juvenile justice system have a mental health condition, and children with mental health issues have significantly higher rates of substance use as adults.

Some children and teens from high-risk areas are identified as having mental health conditions; however, the rate of high-risk factors is high. Research shows that half of all lifetime cases of mental illness begin in adolescence, indicating that half of all children leading to mental illness start to heal, if only a small percentage.

The Task Force discussed the prevalence of mental health conditions among children and youth, specifically all anxiety, bipolar, and depression among teens and young adults. A study published in Pediatrics stated that prevalence of youth ages 10 to 19 years of depression episodes increased percent for to . This trend is expected to continue as the Hispanic population grows.

In addition, the prevalence of anxiety among children and teens was assessed and discussed. The lifetime prevalence of anxiety disorder among children is .% of to adolescents. The lifetime prevalence of severe anxiety disorder is .% of to adolescents.
